Homogenous Products

C.Conlon

Fall 2024

Grad IO

Introduction

One of the earliest exercises in econometrics is the estimation of supply and demand for a homogenous product

- According to Stock and Trebbi (2003) IV regression first appeared in a book by Phillip G. Wright in 1928 entitled *The Tariff on Animal and Vegetable Oils* [neatly tucked away in Appendix B: Supply and Demand for Butter and Flaxseed.]
- Lots of similar studies of simultaneity of supply + demand for similar agricultural products or commodities.

Supply and Demand For Coffee, everything is linear

$$
\begin{aligned}
Q_t^d &= \alpha_0 + \alpha_1 P_t + U_t \\
Q_t^d &= \beta_0 + \beta_1 P_t + V_t \\
Q_t^d &= Q_t^s
\end{aligned}
$$

Solving for P_t, Q_t:

$$
\begin{aligned}
P_t &= \frac{\beta_0 - \alpha_0}{\alpha_1 - \beta_1} + \frac{V_t - U_t}{\alpha_1 - \beta_1} \\
Q_t &= \frac{\alpha_1 \beta_0 - \alpha_0 \beta_1}{\alpha_1 - \beta_1} + \frac{\alpha_1 V_t - \beta_1 U_t}{\alpha_1 - \beta_1}
\end{aligned}
$$

Price is a function of both error terms, and we can't use a clever substitution to cancel things out.

To make things really obvious:

$$Cov(P_t, U_t) = -\frac{Var(U_t)}{\alpha_1 - \beta_1}$$
$$Cov(P_t, V_t) = \frac{Var(V_t)}{\alpha_1 - \beta_1}$$

▸ When demand slopes down ($\alpha_1 < 0$) and supply slopes up ($\beta_1 > 0$) then price is positively correlated with demand shifter U_t and negatively correlated with supply shifter V_t.

$$Cov(P_t, Q_t) = \alpha_1 \, Var \, P_t + Cov(P_t, U_t)$$
$$Cov(P_t, Q_t) = \beta_1 \, Var \, P_t + Cov(P_t, V_t)$$

▸ Bias in OLS estimate (Demand) $Bias(\alpha_1) = \frac{Cov(P_t, U_t)}{Var \, P_t}$.

▸ Bias in OLS estimate (Supply) $Bias(\beta_1) = \frac{Cov(P_t, V_t)}{Var \, P_t}$.

▸ We can actually write both this way when $Cov(U_t, V_t) = 0$:

$$\text{OLS Estimate} = \frac{\alpha_1 \, Var(V_t) + \beta_1 \, Var(U_t)}{Var(V_t) + Var(U_t)}$$

▸ More variation in supply $V_t \rightarrow$ better estimate of demand.

▸ More variation in demand $U_t \rightarrow$ better estimate of supply.

▸ Led Working to say the statistical demand function (OLS) is not informative about the economic demand function (or supply function).

Simultaneity

- For most of you, this was probably a review.
- We know what the solution is going to be to the simultaneity problem.
- We need an excluded instrument that shifts one curve without affecting the other.
- We can use this to form a 2SLS estimate.
- Instead let's look at something a little different...

Simultaneity and Identification

Angrist, Imbens, and Graddy (ReStud 2000).

- ▸ Demand for Whiting (fish) at Fulton Fish Market
- ▸ Do not place functional form restrictions on demand (log-log, log-linear, linear, etc.).
- ▸ "What does linear IV regression of Q on P identify, even if the true (but unknown) demand function is nonlinear"
- ▸ Takes a program evaluation/treatment effects approach to understanding the "causal effect" of price on quantity demanded.
- ▸ Aside: Is there even such a thing as the causal effect of price on quantity demanded?

Four Cases

Ranked in increasing complexity

1. Linear system with constant coefficients

$$q_t^d(p, z, x) = \alpha_0 + \alpha_1 p + \alpha_2 z + \alpha_3 x + \epsilon_t$$
$$q_t^s(p, z, x) = \beta_0 + \beta_1 p + \beta_2 z + \beta_3 x + \eta_t$$

2. Linear system with non-constant coefficients

$$q_t^d(p, z, x) = \alpha_{0t} + \alpha_{1t} p + \alpha_{2t} z + \alpha_{3t} x + \epsilon_t$$
$$q_t^s(p, z, x) = \beta_{0t} + \beta_{1t} p + \beta_{2t} z + \beta_{3t} x + \eta_t$$

3. Nonlinear system with constant shape (separable)

$$q_t^d(p, z, x) = q^d(p, z, x) + \epsilon_t$$
$$q_t^s(p, z, x) = q^s(p, z, x) + \eta_t$$

4. Nonlinear system with time-varying shape (non-separable)

$$q_t^d(p, z, x) = q^d(p, z, x, \epsilon_t)$$
$$q_t^s(p, z, x) = q^s(p, z, x, \eta_t)$$

AIG: Heterogeneity

Two kinds:

1. Heterogeneity depending on value of p fixing t (only relevant in nonlinear models)
2. Heterogeneity across t, fixing p (cases 2 and 4).

- The problem is that we don't generality know which kind of heterogeneity we face.
- Is case (4) hopeless? Or what can we expect to learn?
- Even econometricians struggle with non-linear non-separable models (!)

Assume binary instrument $z_t \in \{0, 1\}$ to make things easier.

1. Regularity conditions on $q_t^d, q_t^s, p_t, z_t, w_t$ first and second moment and is stationary, etc.
   - $q_t^d(p, z, x)$, $q_t^s(p, z, x)$ are continuously differentiable in p.
2. z_t is a valid instrument in q_t^d
   - Exclusion: for all p, t

   $$q_t^d(p, z = 1, x_t) = q_t^d(p, z = 0, x_t) \equiv q_t^d(p, x_t)$$

   ie: conditioning on p_t means no dependence on z_t
   - Relevance: for some period t: $q_t^s(p_t, 1, x_t) \neq q_t^s(p_t, 0, x_t)$.
     ie: z_t actually shifts supply somewhere!
   - Independence: ϵ_t, η_t, z_t are mutually independent conditional on x_t.

Wald Estimator

Focus on the simple case:

- $z \in \{0, 1\}$ where 1 denotes "stormy at sea" and 0 denotes "calm at sea"
- Idea is that offshore weather makes fishing more difficult but doesn't change onshore demand.
- Ignore x (for now at least) or assume we condition on each value of x.

$$\hat{\alpha}_{1,0} \to^p \frac{\mathbb{E}[q_t | z_t = 1] - \mathbb{E}[q_t | z_t = 0]}{\mathbb{E}[p_t | z_t = 1] - \mathbb{E}[p_t | z_t = 0]} \equiv \alpha_{1,0}$$

- If we are in case (1) then we are good. In fact, any IV gives us a consistent estimate of α_1
- If we are in case (4) then $\alpha_{1,0}$ the object we recover, is not an estimator of a structural parameter.
- Moreover, this is at best a LATE, and thus it differs depending on which instrument we use!

AGI: Negative Results

▸ Should we divorce structural estimation from estimating "deep" population parameters (as suggested by Lucas critique)?

▸ Authors make the point that IV estimator identifies something about relationship between p and q, without identifying deep structural parameters?

▸ In IO this is a somewhat heretical idea (especially to start the course with).

In order to interpret the Wald estimator $\alpha_{1,0}$ we make some additional economic assumptions on the structure of the problem:

1. Observed price is market clearing price $q_t^d(p_t) = q_t^s(p_t, z_t)$ for all t. (This means no frictions!).

2. "Potential prices": for each value of z there is a unique market clearing price

$$\forall z, t : \tilde{p}(z,t) \text{ s.t. } q_t^d(\tilde{p}(z,t)) = q_t^s(\tilde{p}(z,t), z).$$

$\tilde{p}(z,t)$ is the potential price under any counterfactual (z,t)

▸ Just like in IV we need denominator to be nonzero so that $E[p_t|z_t = 1] \neq E[p_t|z_t = 0]$.

▸ Other key assumption is the familiar monotonicity assumption

  ▸ $\tilde{p}(z, t)$ is weakly increasing in z.
  ▸ Just like in program evaluation this is the key assumption. There it rules out "defiers" here it allows us to interpret the average slope as $\alpha_{1,0}$.
  ▸ Assumption is untestable because you do not observe both potential outcomes $\tilde{p}(0, t)$ and $\tilde{p}(1, t)$ (same as in program evaluation).
  ▸ Any story about IV is just a story! (Always the case!) unless we have repeated observations on the same individual.

The key result establishes that the numerator of $\alpha_{1,0}$:

$$\mathbb{E}[q_t|z_t = 1] - \mathbb{E}[q_t|z_t = 0] = \mathbb{E}_t\left[\int_{\tilde{p}(0,t)}^{\tilde{p}(1,t)} \frac{\partial q_t^d(s)}{\partial s} d s\right]$$

▸ For each t we average over the slope of demand curve among the two potential prices: $\int_{\tilde{p}(0,t)}^{\tilde{p}(1,t)} \frac{\partial q_t^d(s)}{\partial s} d s$

▸ This range could differ for each t.

▸ Then we average this average over all t.

FIGURE 1

Changing demand functions outside the range of equilibrium prices

What did we learn?

- $\alpha_{1,0}$ only provides information about demand curve in range of potential price variation induced by the instrument.

- Don't know anything about demand curve outside this range!

- For different instruments z, $\alpha_{1,0}$ has a different interpretation like the LATE does. (Different from the linear model where anything works!).

- This is a bit weird: different cost shocks could trace out different paths along the demand curve– why do we care if price change came from a tax change or an input price change? Are they tracing out different subpopulations?

- We need monotonicity so that we know the range of integration $\tilde{p}(0,t) \to \tilde{p}(1,t)$ instead of $\tilde{p}(1,t) \to \tilde{p}(0,t)$

- Observations where $\tilde{p}(0,t) = \tilde{p}(1,t)$ don't factor into the average but we don't know what these observations are because potential prices are unobserved! What is the relevant sub-sample?

$$\alpha_{1,0} = \frac{\mathbb{E}[\int_{\tilde{p}(0,t)}^{\tilde{p}(1,t)} \frac{\partial q_t^d(s)}{\partial s} ds]}{\mathbb{E}\tilde{p}(1,t) - \mathbb{E}\tilde{p}(0,t)}$$

$$\rightarrow \int_0^\infty E\left[\frac{\partial q_t^d(s)}{\partial s} | s \in [\tilde{p}(0,t), \tilde{p}(1,t)]\right] \omega(s) ds$$

▸ given t average the slope of q_t^d from $\tilde{p}(0,t)$ to $\tilde{p}(1,t)$

▸ given price $s \in [\tilde{p}(0,t), \tilde{p}(1,t)]$ average $q_t^d(s)$ across t. (randomness is due to ϵ_t).

▸ Weight $\omega(s)$ is not a function of t but it is largest for prices most likely to fall between $\tilde{p}(0,t)$ and $\tilde{p}(1,t)$.

▸ Case (2): $q_t^d(p) = \alpha_{0t} + \alpha_{1t}p + \epsilon_t$.

$$\alpha_{1,0} = \frac{\mathbb{E}[\alpha_{1t}(\tilde{p}(1,t) - \tilde{p}(0,t))]}{\mathbb{E}\tilde{p}(1,t) - \mathbb{E}\tilde{p}(0,t)} \neq \mathbb{E}\alpha_{1,t}$$

We need mean independence

AGI: Nonlinear IV

▸ Suppose we had a continuous z instead, now we can do a full nonparametric IV estimator.

$$a(z) = \lim_{\nu \to 0} \frac{\mathbb{E}(q_t|z) - \mathbb{E}(q_t|z-\nu)}{\mathbb{E}(p_t|z) - \mathbb{E}(p_t|z-\nu)}$$

▸ Use a kernel to estimate $\hat{q}|z$ and $\hat{p}|z$

$$\alpha'(z) = \frac{\hat{q}'(z)}{\hat{p}'(z)} \approx \frac{\hat{q}'(z+h) - \hat{q}(z)}{\hat{p}'(z+h) - \hat{p}(z)}$$

AGI: Takeaways

▸ When you have a parametric model, you don't need these results because we can define whatever (nonlinear) parametric functional form we want.

▸ There we will focus on parsimonious and realistic parametric functional forms. (this is the rest of the course)

▸ If we don't have a parametric model, then these show us that linear IV estimators give us some average (a particular one!) of slopes.

▸ Caveat: this only works for a single product. In the multi-product case things are a lot more complicated

  ▸ For multiproduct oligopoly it is much harder to satisfy the monotonicity condition. Why?
